

Climate Time Machine – Concept & Working Document

Project Overview

Climate Time Machine is an interactive web-based experience that allows users to visualize how their city may change over time due to climate change. The project focuses on visual storytelling rather than raw data, helping users understand climate impact at a local level.

Core Concept

The idea is to make climate change personal. By showing present vs future visuals of cities, users can better understand long-term environmental consequences and how human actions influence outcomes.

How the Application Works

Users select a city, open a modal view, compare present and future conditions, and switch between emission scenarios. The modal-based design keeps users focused and engaged.

User Experience Philosophy

The UI is minimal, dark, and immersive. The goal is clarity, engagement, and accessibility for both technical and non-technical users.

Technical Workflow

Built using HTML, CSS, and JavaScript with modular logic and lightweight architecture for scalability.

Why Modal-Based Design

Modals allow focused storytelling, easier comparison, and smoother interaction without page reloads.

Future Scope

Plans include real-time climate APIs, more cities, animated timelines, and actionable climate insights.
